**Date:** August 2, 2026

**Document Ref:** NEXA-SBW-2026-ASIL-D

**Version:** v1.2.0

**System:** Synapse Steer-by-Wire (SbW) Core

### Abstract

This document presents the functional and technical safety specification for the **Synapse Steer-by-Wire (SbW)** system developed by **Nexa Automotive Controls** and **Vertex Systems** for the **Meridian EV** platform. Formulated in compliance with the road vehicle functional safety standard **ISO 26262:2018**, this specification documents the Hazard Analysis and Risk Assessment (HARA), defining three Automotive Safety Integrity Level D (ASIL D) Safety Goals: preventing unintended self-steering torque, avoiding complete loss of steering assistance, and preventing mechanical steering rack lockups. Functional Safety Requirements (FSRs) are derived and allocated to the Hand Wheel Actuator (HWA) and Road Wheel Actuator (RWA) subsystems. Furthermore, the Technical Safety Concept (TSC) describes a dual-channel fail-operational system architecture, verified using a real-time Hardware-in-the-Loop (HIL) testing environment. Diagnostic coverage metrics and fault tolerant time intervals (FTTI) are detailed alongside system schematics and verification test matrices, proving compliance with ISO 26262.

# 1 Introduction

The deployment of steer-by-wire (SbW) technology is a pivotal advancement in modern electric and autonomous vehicles, facilitating weight reduction, design flexibility, and seamless integration with advanced driver assistance systems (ADAS) [2]. However, because SbW systems eliminate the physical mechanical steering column connecting the steering wheel to the steering rack, the integrity of the electrical control system is critical for vehicle control.

This document defines the functional and technical safety specification for the **Synapse Steer-by-Wire (SbW)** system developed by **Nexa Automotive Controls** in partnership with **Vertex Systems**. The target application is the **Meridian EV** platform, an electric vehicle featuring high automation capabilities. This specification is designed to satisfy the requirements of the international standard for road vehicle functional safety, **ISO 26262:2018** [1].

## 1.1 System Scope and Boundary

The Synapse SbW system consists of two primary physical sub-assemblies:

1. **Hand Wheel Actuator (HWA)**: Contains torque and angle sensors to capture the driver's steering intent and a feedback motor to simulate road forces and provide steering feel.
2. **Road Wheel Actuator (RWA)**: Comprises redundant electric motors, steering rack position sensors, and microcontrollers to physically actuate the steering linkages.

The boundary of this safety specification covers the dual-channel communication bus (FlexRay), the HWA/RWA microcontrollers, the torque/position sensors, and the actuation power electronics.

## 1.2 Document Objectives

The objectives of this safety specification are:

- To document the Hazard Analysis and Risk Assessment (HARA) and establish Safety Goals (SGs).
- To specify the Functional Safety Requirements (FSRs) allocated to the HWA and RWA.
- To define the Technical Safety Concept (TSC), including fault detection mechanisms, fail-operational strategies, and degraded modes of operation.
- To outline the verification and validation (V&V) milestones for system integration.

## 1.3 Target Audience

This document is intended for systems safety engineers, hardware architects, embedded software developers, and safety assessors responsible for validating the functional safety of the steering control loop.

## 2 Hazard Analysis and Risk Assessment

A systematic Hazard Analysis and Risk Assessment (HARA) was performed in accordance with ISO 26262-3:2018 [1] to identify potential hazardous events resulting from malfunctions in the steer-by-wire system. Each identified hazard is analyzed across various operational situations, evaluating Severity ( $S$ ), Probability of Exposure ( $E$ ), and Controllability ( $C$ ).

### 2.1 Risk Classification Parameters

The hazard classification is conducted using the standard rating levels defined below:

- **Severity ( $S$ ):** Rated from  $S0$  (no injury) to  $S3$  (life-threatening or fatal injuries).
- **Exposure ( $E$ ):** Rated from  $E0$  (incredibly unlikely) to  $E4$  (high probability, everyday driving).
- **Controllability ( $C$ ):** Rated from  $C0$  (easy to control) to  $C3$  (difficult to control or uncontrollable by an average driver).

The combination of these parameters determines the Automotive Safety Integrity Level (ASIL), ranging from ASIL A (lowest) to ASIL D (highest). If a hazard does not require safety measures under ISO 26262, it is classified as Quality Management (QM).

### 2.2 Hazard Identification and ASIL Determination

Table 1 details the hazards evaluated for the Synapse SbW control loop. The worst-case operational situations are selected to determine the safety requirements.

Table 1: Hazard Analysis and Risk Assessment (HARA) for Steer-by-Wire control loop.

| ID    | Hazard Description                                | Operational Situation                         | S  | E  | C  | ASIL   |
|-------|---------------------------------------------------|-----------------------------------------------|----|----|----|--------|
| HZ_01 | Unintended self-steering (spurious torque output) | Highway driving at high speed ( $> 100$ km/h) | S3 | E4 | C3 | ASIL D |
| HZ_02 | Sudden, complete loss of steering assistance      | Sharp cornering on mountain roads             | S3 | E4 | C3 | ASIL D |
| HZ_03 | Mechanical lock-up of the RWA steering rack       | Normal city driving with pedestrians nearby   | S3 | E4 | C3 | ASIL D |
| HZ_04 | Incorrect feedback torque generated at HWA        | Normal highway driving (spurious vibrations)  | S1 | E4 | C1 | QM     |
| HZ_05 | Delayed response of road wheels to driver input   | Overtaking maneuver on a two-lane road        | S3 | E3 | C3 | ASIL C |

### 2.3 Safety Goals (SGs)

Based on the identified hazards, the following Safety Goals (SGs) are established for the steering system. These goals represent the top-level safety requirements that must be met to avoid the hazards.

**Safety Goal 1 (SG\_01): Prevent Unintended Self-Steering**

**Safety Integrity Level:** ASIL D

**Safe State:** Disable affected actuator channel, initiate standby channel, notify driver.

**FTTI:** 50 ms (Fault Tolerant Time Interval)

**Safety Goal 2 (SG\_02): Prevent Complete Loss of Steering Assistance**

**Safety Integrity Level:** ASIL D

**Safe State:** Transition to degraded mode (50% power assist), signal visual warning.

**FTTI:** 100 ms

**Safety Goal 3 (SG\_03): Prevent Physical Steering Lock**

**Safety Integrity Level:** ASIL D

**Safe State:** Mechanically decouple faulty channel, maintain main steering path.

**FTTI:** 15 ms (Immediate response required)

### 3 Functional Safety Requirements

The top-level Safety Goals are refined into Functional Safety Requirements (FSRs), which define the safety-related functions and diagnostic constraints for the steer-by-wire subsystems. These requirements are allocated to the Hand Wheel Actuator (HWA), the Road Wheel Actuator (RWA), and the communication bus.

#### 3.1 FSR Refinement Strategy

To achieve the high reliability required for ASIL D targets, a multi-tier redundancy and diagnostic concept is employed:

- **Dual-Channel Sensory Paths:** Sensor inputs are acquired via independent physical channels with diverse sensing principles (e.g., optical and magnetic).
- **Diagnostic Coverage (DC):** Must exceed 99% for ASIL D paths within the Fault Tolerant Time Interval (FTTI) [3].
- **Logical Execution Checks:** Microcontrollers must execute software safety functions on dual-core lockstep hardware with hardware-enforced memory protection units (MPUs).

#### 3.2 Functional Safety Requirements Allocation

Table 2 maps the FSRs to the respective subsystems, establishing the compliance trace matrix.

Table 2: Functional Safety Requirements (FSR) Allocation Matrix.

| Req ID     | Requirement Description                                                                                         | Allocation     | Safety Goal  | ASIL   |
|------------|-----------------------------------------------------------------------------------------------------------------|----------------|--------------|--------|
| FSR_HWA_01 | HWA shall monitor driver torque inputs using dual-channel diverse sensors with diagnostic coverage > 99%.       | HWA Sensors    | SG_01        | ASIL D |
| FSR_HWA_02 | HWA controller shall disable feedback motor torque if spurious movement is detected in the steering wheel.      | HWA Actuator   | SG_01        | ASIL D |
| FSR_RWA_01 | RWA shall monitor rotor position and torque from both motor channels to cross-validate operational outputs.     | RWA Controller | SG_01, SG_02 | ASIL D |
| FSR_RWA_02 | RWA shall perform diagnostic self-tests on power electronics bridges during system startup and every key cycle. | RWA Inverter   | SG_02        | ASIL D |
| FSR_RWA_03 | RWA shall mechanically isolate a jammed motor winding via an automatic coil-decoupling relay.                   | RWA Actuator   | SG_03        | ASIL D |
| FSR_COM_01 | Communication between HWA and RWA shall use a dual-channel FlexRay bus with active CRC and frame counters.      | FlexRay Bus    | SG_01, SG_02 | ASIL D |

#### 3.3 Technical Safety Requirements (TSRs)

Functional safety requirements are further translated into Technical Safety Requirements (TSRs) to guide the hardware and software design:

1. **TSR\_HW\_01:** The torque sensor signals shall be transmitted via Sentinel-bus protocol

with a 16-bit Cyclic Redundancy Check (CRC).

2. **TSR\_SW\_01:** Software executing on the safety microcontrollers shall implement a three-layer monitoring architecture:
  - Layer 1: Functional control path (torque control).
  - Layer 2: Independent monitoring path (cross-checking torque limits).
  - Layer 3: Processor self-tests, hardware watchdogs, and memory testing.
3. **TSR\_HW\_02:** The steering motor shall be a dual-wind permanent magnet synchronous motor (PMSM) with isolated power electronics bridges to ensure full drive capability if one winding fails.

## 4 Technical Safety Concept and System Architecture

The Synapse SbW system implements a fail-operational architecture designed to tolerate single-point hardware and software faults without compromising primary steering control. To satisfy the ASIL D requirements, both physical power paths and electrical signaling paths are fully redundant and galvanically isolated.

### 4.1 Redundant System Architecture

The system layout features two independent control channels that operate in parallel. Under nominal conditions, both channels contribute equally to active steering and cross-monitor each other. If one channel detects a critical fault, it disables itself and isolates its winding, while the standby channel immediately assumes 100% steering control.

Figure 1 displays the logical block diagram of the technical safety concept.

Figure 1: Steer-by-Wire fail-operational architecture schematic showing dual-channel signal pathways.

### 4.2 Cross-Channel Monitoring and Diagnostic Concept

To ensure instant fault containment, the microcontrollers exchange status bytes and control signals over a high-speed local serial link. The main diagnostics checked include:

- **E2E Communication Safeguards:** Data packets on the FlexRay bus include sequence numbers and a 16-bit CRC to detect signal loss, corruption, or delays.
- **Plausibility Check of Sensor Input:** The torque values from Sensor A and Sensor B are compared. If the variance exceeds 5% for more than 4 ms, a sensor fault state is declared.
- **Power Stage Diagnostics:** Gate driver diagnostic signals are checked continuously to verify proper execution of inverter switching patterns.

### 4.3 Transition to Safe State

If a diagnostic error is flagged, the system executes the safe state transition matrix described in Table 3.

Table 3: Safe State Transition Matrix for Steer-by-Wire Control Channels.

| Diagnostic Failure Trigger                   | Active State     | Next Safe State      | Degraded Functionality                                                       |
|----------------------------------------------|------------------|----------------------|------------------------------------------------------------------------------|
| Single torque sensor channel open-circuit    | Nominal Dual-Ch. | Single-Channel Mode  | Full steering power assist; yellow dashboard warning lit.                    |
| FlexRay Channel A communication timeout      | Nominal Dual-Ch. | Single-Channel Bus   | Full power assist using FlexRay Channel B; steering response unchanged.      |
| RWA Inverter Phase Short-Circuit (Channel A) | Nominal Dual-Ch. | Degraded Backup Mode | Channel A isolated; Channel B drives steering with 50% power assist.         |
| Double-channel sensor failure (Dual loss)    | Nominal Dual-Ch. | Safe Shutdown State  | Steering assist disabled; physical steering rack locked in neutral position. |

## 5 Verification and Validation Concept

Compliance with ISO 26262 ASIL D demands rigorous verification and validation (V&V) procedures across all stages of system development. The Synapse SbW safety concept is validated through a combination of simulation, laboratory testing, and vehicle-level verification.

### 5.1 V&V Testing Methodologies

The validation plan employs three distinct testing paradigms:

1. **Software-in-the-Loop (SIL):** Automated regression testing of the control and safety algorithms in a simulated vehicle dynamics environment.
2. **Hardware-in-the-Loop (HIL):** Testing the physical HWA and RWA ECUs in a real-time lab setup where hydraulic actuators simulate physical tire-road interactions.
3. **Vehicle-level Track Testing:** Functional verification on proving grounds to evaluate driver controllability and system response under degraded modes.

### 5.2 Fault Injection Testing on HIL Test Bench

Fault injection testing is a critical validation method used to prove that the system transitions to the designated safe state within the FTTI limit when a malfunction occurs. Table 4 lists the key fault injection scenarios executed during test bench verification.

Table 4: Key fault injection scenarios and safety responses.

| Test ID    | Fault Simulated                                    | Expected Safe Response                                                       | Safety Goal  | FTTI Target |
|------------|----------------------------------------------------|------------------------------------------------------------------------------|--------------|-------------|
| FIT_HWA_01 | Spurious voltage offset on Torque Sensor Channel A | Control switches to Channel B; driver torque continues without interruption. | SG_01        | 50 ms       |
| FIT_RWA_02 | Phase loss on Motor Winding A inverter bridge      | HSI isolates Channel A; steering continues using Channel B with half-power.  | SG_02        | 100 ms      |
| FIT_COM_03 | High electromagnetic noise on FlexRay Channel A    | System rejects corrupted frames and switches to Channel B.                   | SG_01, SG_02 | 50 ms       |
| FIT_SYS_04 | Microcontroller lockup (forced watchdog timeout)   | Safety monitor isolates the faulty MCU; standby MCU takes control.           | SG_01, SG_02 | 100 ms      |

### 5.3 Safety Case Milestones and Audits

A formal safety case is prepared compile safety evidence that all SGs are met. The safety development lifecycle is audited at key milestones by external certifiers:

- **Milestone 1 (Gate 1):** Concept Phase Audit — Focuses on the HARA, Safety Goals, and Functional Safety Concept.
- **Milestone 2 (Gate 2):** System Design Review — Audits the technical safety concept and schematic designs.

- **Milestone 3 (Gate 3):** Safety Case Verification — Reviews the compilation of testing logs, diagnostic coverage analysis, and HIL reports.
